Introduction

Alpha₁-antitrypsin (AAT) deficiency is a rare, inherited disease that is caused by a change (mutation) in the SERPINA1 gene. The SERPINA1 gene provides instructions to create alpha₁-antitrypsin which prevents the destruction of elastin in the lungs, liver, and skin. In the lungs this elastin deficiency can cause early onset chronic obstructive pulmonary disease (COPD) (i.e., emphysema). Cigarette smoke can rapidly accelerate damage to the lungs in individuals with AAT deficiency. Standard treatment includes exercise programs, nutritional support, drugs, and avoidance of cigarette smoke. When the AAT deficiency becomes severe drugs called alpha₁-proteinase inhibitors can be used to increase the AAT levels which may slow the decline in lung function and delay any further damage. There are currently four Food and Drug Administration (FDA) approved alpha₁-proteinase inhibitors available which are Aralast NP, Glassia, Prolastin-C, and Zemaira. This policy describes when drugs used to treat emphysema due to severe AAT deficiency may be considered medically necessary.

Note: The Introduction section is for your general knowledge and is not to be taken as policy coverage criteria. The rest of the policy uses specific words and concepts familiar to medical professionals. It is intended for providers. A provider can be a person, such as a doctor, nurse, psychologist, or dentist. A provider also can be a place where medical care is given, like a hospital, clinic, or lab. This policy informs them about when a service may be covered.

Policy Coverage Criteria

We will review specific intravenous (IV) and injectable drugs for medical necessity for all ages.

For those age 13 and older, we also will review the site of service for medical necessity. Site of service is defined as the location where the drug is administered, such as a hospital-based outpatient setting, an infusion center, a physician's office, or at home. Click [here](#) to be directed to the site of service review criteria.

Drugs subject to site of service review addressed in this policy are:

- Aralast NP (alpha₁-proteinase inhibitor [human]) IV
- Glassia (alpha₁-proteinase inhibitor [human]) IV
- Prolastin-C (alpha₁-proteinase inhibitor [human]) IV
- Zemaira (alpha₁-proteinase inhibitor [human]) IV

Site of Service Administration	Medical Necessity
Medically necessary sites of service <ul style="list-style-type: none"> • Physician's office • Infusion center • Home infusion 	<p>IV infusion therapy of various medical or biologic agents will be covered in the most appropriate, safe and cost-effective site:</p> <ul style="list-style-type: none"> • These are the preferred medically necessary sites of service for specified drugs.

Documentation Requirements

The individual's medical records submitted for review for all conditions should document that medical necessity criteria are met. The record should include the following:

- Office visit notes that contain the diagnosis, relevant history, physical evaluation, and medication history

Coding

Code	Description
HCPCS	
J0256	Injection, alpha 1-proteinase inhibitor, human, 10 mg, not otherwise specified (Aralast NP, Prolastin-C, Zemaira)
J0257	Injection, alpha 1 proteinase inhibitor (human), (Glassia), 10 mg

Note: CPT codes, descriptions and materials are copyrighted by the American Medical Association (AMA). HCPCS codes, descriptions and materials are copyrighted by Centers for Medicare Services (CMS).

Related Information

Consideration of Age

The ages stated in this policy for which Aralast NP, Glassia, Prolastin-C, and Zemaira are considered medically necessary are based on the ages approved in the US Food and Drug Administration (FDA) labeling.

Benefit Application

This policy is managed through the medical benefit.

Evidence Review

Background

Alpha₁-antitrypsin (AAT) deficiency is a chronic, autosomal, co-dominant hereditary disorder characterized by reduced levels of AAT in the blood and lungs. Smoking is an important risk factor for the development of emphysema in individuals with AAT deficiency. Because emphysema affects many, but not all individuals with the more severe genetic variants of AAT deficiency, augmentation therapy with alpha₁-proteinase inhibitor (human) is indicated only in individuals with severe AAT deficiency who have clinically evident emphysema.

A large number of phenotypic variants of AAT deficiency exist, not all of which are associated with the clinical disease. Approximately 95% of identified AAT deficient individuals have the PiZZ variant, typically characterized by AAT serum levels <35% of normal. Individuals with the Pi(null)(null) variant have no AAT protein in their serum. Individuals with the lack of, or low, endogenous serum levels of AAT (i.e., below 11 μM) manifest a significantly increased risk for development of emphysema above the general population background risk. In addition, PiSZ individuals, whose serum AAT levels range from approximately 9 to 23 μM are considered to have moderately increased risk for developing emphysema, regardless of whether their serum AAT levels are above or below 11 μM.

Augmenting the levels of functional protease inhibitor by intravenous infusion is an approach to therapy for individuals with AAT deficiency. However, the efficacy of augmentation therapy in affecting the progression of emphysema has not been demonstrated in randomized, controlled clinical trials. The intended theoretical goal is to provide protection to the lower respiratory tract by correcting the imbalance between neutrophil elastase and protease inhibitors. Whether augmentation therapy with any alpha₁-proteinase inhibitor product actually protects the lower respiratory tract from progressive emphysematous changes has not been conclusively demonstrated in adequately powered, randomized controlled clinical trials. Although the maintenance of blood serum levels of AAT (antigenically measured) above 11 μM has been historically postulated to provide therapeutically relevant antineutrophil elastase protection, this

has not been proven. Individuals with severe AAT deficiency have been shown to have increased neutrophil and neutrophil elastase concentrations in lung epithelial lining fluid compared to normal PiMM individuals, and some PiSZ individuals with AAT above 11 μ M have emphysema attributed to AAT deficiency. These observations underscore the uncertainty regarding the appropriate therapeutic target serum level of AAT during augmentation therapy.

Summary of Evidence

Aralast NP (alpha1-proteinase inhibitor [human])

Description

Aralast NP contains approximately 2% alpha₁-PI with truncated C-terminal lysine (removal of Lys394). Aralast NP is a sterile, lyophilized preparation of purified human alpha₁-proteinase inhibitor. Aralast NP is prepared from large pools of human plasma by using the cold ethanol fractionation process, followed by purification steps including polyethylene glycol and zinc chloride precipitations and ion exchange chromatography.

Dosage and Administration

Administer 60 mg/kg body weight of Aralast NP once weekly by intravenous infusion. The infusion rate of Aralast NP should not exceed 0.2 mL/kg/min, and as determined by the response and comfort of the individual.

Efficacy

A clinical trial (Aralast versus Prolastin trial) was conducted to compare the predecessor product Aralast to a commercially available preparation of alpha₁-PI (Prolastin) in 28 subjects with congenital alpha₁-PI deficiency and emphysema, who had not received alpha₁-PI augmentation therapy within the preceding six months.

Subjects were randomized to receive either Aralast or Prolastin, 60 mg/kg intravenously per week for 10 consecutive weeks. Following their first 10 weekly infusions, the subjects who were receiving Prolastin were switched to Aralast while those who already were receiving Aralast continued to receive it.

Following weekly augmentation therapy with Aralast or Prolastin, a gradual increase in peak and trough serum alpha₁-PI levels was noted, with stabilization after several weeks. The metabolic half-life of Aralast was 5.9 days. Serum anti-neutrophil elastase capacity (ANEC) trough levels rose substantially in all subjects by Week 2, and by Week 3, serum ANEC trough levels exceeded 11 μM in the majority of subjects. With few exceptions, levels in both treatment groups remained above this level in individual subjects for the duration of the period Weeks 3 through 24. Although only five of fourteen subjects (35.7%) receiving Aralast had BALs meeting acceptance criteria for analysis at both baseline and Week 7, a statistically significant increase in the antigenic level of alpha₁-PI in epithelial lining fluid (ELF) was observed. No statistically significant increase in the ANEC in the ELF was detected. It was concluded that at a dose of 60 mg/kg administered intravenously once weekly, Aralast and Prolastin had similar effects in maintaining target serum alpha₁-PI trough levels and increasing antigenic levels of alpha₁-PI in the ELF with maintenance augmentation therapy.

Adverse Reactions

The most common adverse reactions occurring in ≥5% of infusions in clinical studies were headache, musculoskeletal discomfort, vessel puncture site bruise, nausea, and rhinorrhea.

Glassia (alpha1-proteinase inhibitor [human])

Description

Glassia is a sterile, ready to use, liquid preparation of purified human alpha₁-proteinase inhibitor (PI). The solution contains 2% active alpha₁-PI in a phosphate-buffered saline solution. The specific activity of Glassia is ≥ 0.7 mg functional alpha₁-PI per mg of total protein. No less than 90% of the alpha₁-PI in Glassia is of the monomeric form as measured by size-exclusion chromatography. Glassia is prepared from human plasma obtained from US-licensed plasma collection centers by a modified version of the cold ethanol fractionation process and the alpha₁-PI is then purified using chromatographic methods.

Dosage and Administration

Administer 60 mg/kg body weight of Glassia once weekly by intravenous infusion. The infusion rate of Glassia should not exceed 0.2 mL/kg/min, and as determined by the response and

comfort of the individual. The recommended dosage of 60 mg/kg at a rate of 0.2 mL/kg/min will take approximately 15 minutes to infuse.

Efficacy

A randomized, double-blind trial with a partial cross-over was conducted to compare Glassia to a commercially available preparation of alpha₁-PI (Prolastin) in 50 alpha₁-PI deficient subjects. The trial objectives were to demonstrate that the pharmacokinetics of antigenic and/or functional alpha₁-PI in Glassia were not inferior to those of the control product, to determine whether Glassia maintained antigenic and/or functional plasma levels of at least 11 µM (57 mg/dL) and to compare alpha₁-PI trough levels (antigenic and functional) over 6 infusions.

For inclusion in the trial, subjects were required to have lung disease related to alpha₁-PI deficiency and 'at-risk' alleles associated with alpha₁-PI plasma levels < 11 µM. Subjects already receiving alpha₁-PI therapy were required to undergo a 5-week wash-out period of exogenous alpha₁-PI prior to dosing.

Fifty subjects received either Glassia (33 subjects) or the comparator product (17 subjects) at a dose of 60 mg/kg intravenously per week for 12 consecutive weeks. From Week 13 to Week 24 all subjects received open-label weekly infusions of Glassia at a dose of 60 mg/kg.

Trough levels of functional and antigenic alpha₁-PI were measured prior to treatment, at baseline and throughout the trial until Week 24. The median trough alpha₁-PI values for Weeks 7-12 for subjects receiving Glassia were 14.5 µM (range: 11.6 to 18.5 µM) for antigenic and 11.8 µM (range: 8.2 to 16.9 µM) for functional alpha₁-PI. Eleven of 33 subjects (33.3%) receiving Glassia had mean steady-state functional alpha₁-PI levels below 11 µM. Glassia was shown to be non-inferior to the comparator product.

Serum alpha₁-PI trough levels rose substantially in all subjects by Week 2 and were comparatively stable during Weeks 7 to 12. All subjects receiving Glassia had mean serum trough antigenic alpha₁-PI levels greater than 11 µM during Weeks 7-12.

A subset of subjects in both treatment groups (n = 7 for subjects receiving Glassia) underwent broncho-alveolar lavage (BAL) and were shown to have increased levels of antigenic alpha₁-PI and alpha₁-PI - neutrophil elastase complexes in the epithelial lining fluid at Week 10-12 over levels found at baseline, demonstrating the ability of the product to reach the lung.

The clinical efficacy of Glassia in influencing the course of pulmonary emphysema or the frequency, duration, or severity of pulmonary exacerbations has not been demonstrated in randomized, controlled clinical trials.

Adverse Reactions

The most common adverse reactions (>0.5% of infusions) in clinical trials were headache and upper respiratory infection.

Prolastin-C (alpha1-proteinase inhibitor [human])

Description

Prolastin-C is a sterile, white to beige-colored concentrate of alpha₁-PI in lyophilized powder form for reconstitution for intravenous infusion. Each vial contains approximately 1,000 mg of functionally active alpha₁-PI as determined by capacity to neutralize porcine pancreatic elastase. The specific activity of Prolastin-C is ≥ 0.7 mg functional alpha₁-PI per mg of total protein. Prolastin-C has a purity of $\geq 90\%$ alpha₁-PI (alpha₁-PI protein/total protein). When reconstituted with 20 mL of Sterile Water for Injection, USP, Prolastin-C has a pH of 6.6–7.4, a sodium content of 100–210 mM, a chloride content of 60–180 mM and a sodium phosphate content of 13–25 mM. Prolastin-C contains no preservative. Prolastin-C is produced from pooled human plasma through modifications of the Prolastin process using purification by polyethylene glycol (PEG) precipitation, anion exchange chromatography, and cation exchange chromatography.

Dosage and Administration

Administer 60 mg/kg body weight of Prolastin-C once weekly by intravenous infusion. The infusion rate of Prolastin-C should not exceed 0.08 mL/kg/min, and as determined by the response and comfort of the individual.

Efficacy

The clinical efficacy of Prolastin-C in influencing the course of pulmonary emphysema or pulmonary exacerbations has not been demonstrated in adequately powered, randomized, controlled clinical trials.

A total of 23 subjects with the PiZZ variant and documented emphysema were studied in a single-arm, open label clinical trial with Prolastin, the predecessor product. Nineteen of the subjects received Prolastin, 60 mg/kg, once weekly for up to 26 weeks (average 24 weeks). Blood

levels of alpha₁-PI were maintained above 11 μM. Bronchoalveolar lavage studies demonstrated statistically significant increased levels of alpha₁-PI and functional anti-neutrophil elastase capacity (ANEC) in the epithelial lining fluid of the lower respiratory tract of the lung, as compared to levels prior to dosing.

Adverse Reactions

The most common adverse reaction during clinical trials in > 5% of subjects was upper respiratory tract infection.

Zemaira (alpha1-proteinase inhibitor [human])

Description

Zemaira is a sterile, white to off-white, lyophilized preparation of purified alpha₁-proteinase inhibitor (human) (alpha₁-PI), also known as alpha -antitrypsin, to be reconstituted and administered by the intravenous route. The specific activity of Zemaira is ≥0.7 mg of functional alpha₁-PI per milligram of total protein. The purity (total alpha₁-PI/total protein) is ≥90% alpha₁-PI. Each vial contains approximately 1000 mg, 4000 mg, or 5000 mg of functionally active alpha₁-PI. The measured amount per vial of functionally active alpha₁-PI as determined by its capacity to neutralize human neutrophil elastase (NE) is printed on the vial label and carton. Following reconstitution with 20 mL, 76 mL, or 95 mL of Sterile Water for Injection, USP, the Zemaira solution contains 73 to 89 mM sodium, 33 to 42 mM chloride, 15 to 20 mM phosphate, and 121 to 168 mM mannitol. Hydrochloric acid and/or sodium hydroxide may have been added to adjust the pH. Zemaira contains no preservative.

Dosage and Administration

Administer 60 mg/kg body weight of Zemaira once weekly by intravenous infusion. The infusion rate of Zemaira should not exceed 0.08 mL/kg/min, and as determined by the response and comfort of the individual. The recommended dosage of 60 mg/kg body weight will take approximately 15 minutes to infuse.

Efficacy

Clinical trials were conducted pre-licensure with Zemaira in 89 subjects (59 males and 30 females). The subjects ranged in age from 29 to 68 years (median age 49 years). Ninety-seven percent of the treated subjects had the PiZZ phenotype of alpha₁-PI deficiency, and 3% had the M phenotype. At screening, serum alpha₁-PI levels were between 3.2 and 10.1 μM (mean of 5.6 μM). The objectives of the clinical trials were to demonstrate that Zemaira augments and maintains serum levels of alpha₁-PI above 11 μM (80 mg/dL) and increases alpha₁-PI levels in epithelial lining fluid (ELF) of the lower lung.

In a double-blind, controlled clinical trial to evaluate the safety and efficacy of Zemaira, 44 subjects were randomized to receive 60 mg/kg of either Zemaira or Prolastin once weekly for 10 weeks. After 10 weeks, subjects in both groups received Zemaira for an additional 14 weeks. Subjects were followed for a total of 24 weeks to complete the safety evaluation. The mean trough serum alpha₁-PI levels at steady state (Weeks 7-11) in the Zemaira-treated subjects were statistically equivalent to those in the Prolastin treated subjects within a range of ±3 μM. Both groups were maintained above 11 μM. The mean (range and standard deviation [SD]) of the steady state trough serum antigenic alpha₁-PI level for Zemaira-treated subjects was 17.7 μM (range 13.9 to 23.2, SD 2.5) and for Prolastin-treated subjects was 19.1 μM (range 14.7 to 23.1, SD 2.2). The difference between the Zemaira and the Prolastin groups was not considered clinically significant and may be related to the higher specific activity of Zemaira.

The clinical efficacy of Zemaira or any alpha₁-PI product in influencing the course of pulmonary emphysema or pulmonary exacerbations has not been demonstrated in adequately powered, randomized, controlled clinical trials.

Adverse Reactions

The most common adverse reactions occurring in at least 5% of subjects in all pre-licensure clinical trials were headache, sinusitis, upper respiratory infection, bronchitis, asthenia, cough increased, fever, injection site hemorrhage, rhinitis, sore throat, and vasodilation

2022 Update

Reviewed prescribing information for all drugs listed in policy and information on the management of adults with clinically evident emphysema due to severe hereditary deficiency of alpha₁-PI (alpha₁-antitrypsin deficiency). No new information was identified that would require changes to this policy.

2023 Update

Reviewed prescribing information for all drugs listed in policy. No new evidence found that would require changes to the policy. Removed trademarks from the brand products for the process of standardization.

2024 Update

Reviewed prescribing information for all drugs listed in policy. Added site of service review for Aralast NP, Glassia, Prolastin-C, and Zemaira.
